10,000 BATTERIES

The BESS Is Up and Running on Race Point Road

But Eversource's Battery Energy Storage System never saw duty this winter

BY AMELIA ROTH-DISHY · MAY 17, 2023

PROVINCETOWN — For the first time in years, the Outer Cape managed to avoid major power outages last winter. There were storms — including on Dec. 23, when several East End streets were flooded with salt water, and on Feb. 4, when frozen pipes burst all over town — but they were not exacerbated by a loss of power that would have disabled sump pumps and heating systems as well.

but sits idle most of the time in deregulated markets

because of concerns over market distortion.

- Basis of deregulated markets: competition in electricity generation (Joskow and Schmalensee, 1983).

because of concerns over market distortion.

- Basis of deregulated markets: competition in electricity generation (Joskow and Schmalensee, 1983).
- State legislation requires that generation be split from transmission and distribution, e.g., MA HB5117 (1998), in the hope to remedy a situation in which

> "the **existing regulatory system** results in among the **highest, residential and commercial electricity rates** paid by customers throughout the United States."
> Massachusetts General Court, 1997

because of concerns over market distortion.

Question to assess market distortions: How much battery storage capacity do utilities own?

EIA860, June 2025: US electricity generation capacity – 1300GW, batteries – 33GW, utility-owned – 3.4GW.

Some states experiment with allowing market participation to reduce retail prices.

STATE OF NEW YORK PUBLIC SERVICE COMMISSION

ORDER APPROVING UTILITY-OWNED ASSET PARTICIPATION IN WHOLESALE MARKETS

(Issued and Effective September 9, 2021)

Pomona Substation, Orange & Rockland, NY, 3MW/12MWh

In 2024:

- 12 battery cycles for grid needs, 94 cycles for market participation.
- $23,121 from arbitrage and $71,114 from ancillary services, about **$8/kWh**.
- Battery offline for increased maintenance about 1 day per month.

Geographical scope

Geographical scope

States allowing for market participation:

- MD (2019)
- NY (2021)

- EC (2023): Explore full flexibility potential of energy storage in distribution grids.
- ACER (2025): Create a market for local services that help alleviate distribution grid constraints.

Research program

Quantify the value of **investment deferral** (the grid value) and **arbitrage** and **scarcity supply** (the market value).

1. **Formal model** of market participation constraints for **battery operations** and **investment planning**.
2. **Compare** the grid value to the market value.
3. **Determine storage investments appropriate for distribution needs**.

Inform **state policy**.

Why arbitrage and capacity markets?

Figure 2.21: CAISO Market Monitor Special Report on Battery Storage, 2024

Figure 2.19: CAISO Market Monitor Special Report on Battery Storage, 2024

... because ancillary services markets are saturating (Figgener et al., 2023; Mastropietro et al., 2024).

State of the Art

Actual Operations (Orange & Rockland, 2024)

On a **daily basis**, decide if battery is needed for distribution grid support.

If not, decide if it should be used for market participation.

Academic Studies (PNNL, 2019)

During potential **N-1 contingency hours** maintain state-of-charge at 100%, discharge if contingency arises.

Maximum annual throughput of 150 cycles to maintain warranty listed as further study.

Our Contributions

Model both contingency and noncontingency scenarios. On a daily basis, decide on hourly operations for both scenarios. No need for state-of-charge heuristics. Include storage market participation in planning problems.

Problem Formulation (Operations / Economic Dispatch)

Supply Resources: $\mathcal{R} = \{\mathrm{b}, \mathrm{g}, \mathrm{s}\}$

backup

grid

storage

Demand Resources: $\mathcal{D} = \{\mathrm{g}, \ell, \mathrm{s}\}$

grid

load

storage

Production Decisions: $y^{\mathrm{s}}_{rk}\ \forall r \in \mathcal{R}, k \in \{1, \dots, K\}$

Demand Decisions: $y^{\mathrm{d}}_{rk}\ \forall r \in \mathcal{D}, k \in \{1, \dots, K\}$

Objective: Minimize linear operating costs.

Constraints (standard)**:** Capacity restrictions, nonnegativity, energy balance, charging and discharging losses.

Constraints (**Market participation**)**:**

$$\sum_{r \in \{\mathrm{b},\mathrm{s}\}} y^{\mathrm{s}}_{rk} \leq \left[y^{\mathrm{d}}_{\ell k} - \bar{x}_{\mathrm{g}} \right]^{+} \quad \text{(limited backup and storage)}$$

Problem Formulation (Operations / Economic Dispatch)

Demand Decisions: $y^{\mathrm{d}}_{rk}\ \forall r \in \mathcal{D}, k \in \{1, \dots, K\}$

Objective: Minimize linear operating costs.

Constraints (standard)**:** Capacity restrictions, nonnegativity, energy balance, charging and discharging losses.

Constraints (**Market participation**)**:**

$$\sum_{r \in \{\mathrm{b},\mathrm{s}\}} y^{\mathrm{s}}_{rk} \leq \left[y^{\mathrm{d}}_{\ell k} - \bar{x}_{\mathrm{g}}\right]^{+} \text{ (limited backup and storage)} \iff \max\left\{y^{\mathrm{d}}_{\ell k} - \bar{x}_{\mathrm{g}}, 0\right\} + \sum_{r \in \{\mathrm{b},\mathrm{s}\}} y^{\mathrm{s}}_{rk} \geq 0$$

Problem Formulation (Investment decisions)

Supply Resources: $\mathcal{R} = \{\mathrm{b}, \mathrm{g}, \mathrm{s}\}$

backup

grid

storage

Investment Decisions: $x_{rn}\ \forall r \in \mathcal{R}, n \in \{1, \dots, N\}$

Sample investment costs and existing capacity.

Objective: Minimize nonconvex investment costs.

Constraints (standard)**:** Investment range, nonnegativity, lifetime, contingency-adjusted capacity.

Trade-off:

Lumpy investments with low per-unit costs vs modular investments with high-per unit costs.

Case Study (Nantucket)

Electricity Demand (2024)

Demand peaks on summer afternoons.

Electricity Price (2024)

Price peaks on summer afternoons.

Scarcity Events (2024)

Scarcity happens on summer afternoons.

Analyze:

- Contingency supply mix with and without market participation.

Participation Constraints: Cover Supply Shortfall Only

Limited Backup and Storage (Status Quo)

Storage is only used at times of peak demand.

Storage Supply: 1.7GWh (35 cycles)

Operating Cost: $M 9.6

Full Market Participation

Storage used throughout the year.

Storage Supply: 15.9GWh (331 cycles)

Operating Cost: $M 9.2

Resource Utilization (2025)

Resource Utilization (2025)

Results and Conclusion

1. **Formal model** of market participation constraints for **battery operations** and **investment planning**. → Limit generation to cover shortfalls of grid capacity relative to peak demand.

2. **Compare** the grid value to the market value. → Similar.

3. **Determine storage investments appropriate for distribution needs**. → Via mathematical optimization. Under current market conditions, we find no incentive for extra investment.

Points for Discussion

1. How do these findings resonate with you? Would the tool be useful for you and the regulator?
2. Should deregulated states allow for market participation? What implications would this have?
3. Should distribution companies create price signals for distribution needs or contract storage from third parties?
